A.C. Coupling Capacitor Selection

INTRODUCTION

This application note discusses the various capacitor types available which are suitable for a.c. coupling of audio signals in and out of Wolfson CODECs. The choice is becoming more difficult as parts are getting smaller. A good choice will avoid signal attenuation or distortion.

REQUIREMENTS

In many audio circuits the input or output has a d.c. bias on it. To connect this to another circuit, which may have a different bias voltage, a capacitor is used. This capacitor blocks the d.c. path, but passes the a.c. audio signal. This capacitor is required with Wolfson ADC inputs, DAC outputs and usually headphone drivers.

The value of capacitance required depends on the source/load impedance and the frequency range. In the a.c. coupling situation the capacitor will form part of a high-pass filter, so it is the bass cut-off frequency that is important. If the capacitance is too small, bass response is made worse. The cut-off frequency, at which the signal is attenuated by 3dB, is defined by the following equation:

\[ f_{-3\text{dB}} = \frac{1}{2\pi RC} \]

The table below shows the main two applications. For DAC line outputs, the load impedance may be the traditional 47kΩ, or it may be around 10kΩ (like SCART). For ADC line inputs, the impedance may also go below 10kΩ, depending on the ADC amplifier gain selected. These issues affect the choice of coupling capacitor, depending on the acceptable cut-off frequency.

CAPACITOR DIELECTRICS

It is important to understand about the dielectric (the insulator between the metal plates of the capacitor) and how its behaviour deviates from ideal. If the capacitance is not stable, it can lead to signal distortion.

CERAMIC

Ceramic capacitors are by far the most popular type of capacitor as they are available in small surface-mount packages at low cost. They are most commonly used for decoupling ICs, but are also used in RF applications and some audio applications.

Ceramic capacitors are available in a number of dielectrics. The most common dielectrics are C0G (same as NP0), X7R and Y5V.

C0G gives a very stable capacitance value with varying temperature and voltage. Unfortunately it is only available in smaller values. It is good for the signal path.

X7R is not so stable, but is available in much higher values. Its capacitance varies a little with temperature and d.c. voltage.

Y5V is a poor choice. The temperature range is smaller and it has huge variations of capacitance with voltage.

U2J is a newer dielectric which is nearly as good as C0G, with narrower temperature range, but is available in higher capacitance values. It is primarily applicable in audio low-pass filters.

X5R is a newer dielectric, replacing Y5V with better performance. It is essentially the same as X7R but with reduced temperature range and more d.c.-voltage dependency.

Table 2 Ceramic Dielectric Properties
Figure 2  Ceramic Capacitance vs. d.c. Bias Voltage

Figure 2 shows 1µF 16V 0805 capacitors and how their capacitances vary with voltage. The first (blue) is X7R, second (red) is X5R, third (black) is thicker X5R, fourth (magenta) is Y5V. As you can see, the Y5V capacitance changes greatly with voltage and is only suitable for decoupling low fixed voltages like VMID on our CODECs. X5R shows a big difference between parts and the right one must be chosen for best performance. X7R is the most stable and best choice for performance.

Figure 3  Ceramic Capacitance vs. Temperature

Figure 3 shows the same 1µF 16V capacitors and how their capacitances vary with temperature. As you can see the Y5V capacitance changes greatly with temperature. In a product with elevated temperatures, the cut-off frequency could be adversely affected.
Tantalum capacitors are available in a number of variants. They are generally more expensive than ceramic capacitors but offer greater stability at higher capacitance values, albeit with higher ESR (Equivalent Series Resistance). These features make them preferable over ceramic types in most cases.

Table 3  Tantalum Electrolytic Properties

ALUMINIUM ELECTROLYTIC

Standard aluminium parts are much lower cost than tantalum, but are usually physically bigger. They offer good stability of capacitance with voltage and temperature and have similar ESR, so are recommended where there is enough space.

ALUMINIUM ORGANIC/POLYMER ELECTROLYTIC

These parts offer very good performance at a higher price. If the application permits, these are the preferred choice.
WHY IS THE CAPACITANCE CHANGE WITH D.C. VOLTAGE IMPORTANT?

If a large low-frequency signal is applied to the capacitor, it looks like a slowly-changing d.c. offset. Consider a 2Vrms DAC output at 50Hz. The typical d.c. offset will be 4.5V if the supply is 9V. When the DAC is producing a full-scale waveform, the output is going between 0 and 9V. This means the capacitor sees an effective change in d.c. bias from 0 to 9V. For a ceramic Y5V capacitor, the capacitance changes between 1.25µF and 0.22µF, which means that charge is stored and released in a non-linear fashion, causing signal distortion.

RECOMMENDATIONS

LINE INPUTS AND OUTPUTS

The load impedance is usually >1kΩ, so the higher ESR of electrolytic capacitors is not significant.

To achieve good frequency response with 47kΩ load, 1µF is a minimum requirement. For best performance choose tantalum or aluminium electrolytic. Where space is limited and high performance is not required, use X7R ceramic.

To achieve good frequency response with 10kΩ load, 1µF is a minimum requirement, but 10µF would be better for higher-quality applications. For best performance choose tantalum or aluminium electrolytic. Where space is limited and high performance is not required, use X7R ceramic. For lowest cost, use X5R ceramic, but THD at low frequencies will be worse.

HEADPHONE OUTPUTS

The load impedance is usually 16-32Ω, so the higher ESR of tantalum capacitors is significant for power loss. To achieve good frequency response, 100µF is a minimum requirement, 220µF better. For best performance choose low-ESR tantalum or aluminium electrolytic. ESR under 1Ω would be best for power efficiency. Where space is limited, use microchip tantalum. For lowest cost, use X5R ceramic, but THD at low frequencies will be worse.

Table 4 Recommended Components
CONCLUSION

There are a variety of capacitors available for audio applications. With careful choice, the cost can be optimised for the appropriate size and performance level.

APPLICATION SUPPORT

If you require more information or require technical support, please contact the Wolfson Microelectronics Applications group through the following channels:

Email: apps@wolfsonmicro.com
Telephone Apps: (+44) 131 272 7070
Fax: (+44) 131 272 7001
Mail: Applications Engineering at the address on the last page

or contact your local Wolfson representative.

Additional information may be made available on our web site at:

IMPORTANT NOTICE

Wolfson Microelectronics plc (WM) reserve the right to make changes to their products or to discontinue any product or service without notice, and advise customers to obtain the latest version of relevant information to verify, before placing orders, that information being relied on is current. All products are sold subject to the WM terms and conditions of sale supplied at the time of order acknowledgement, including those pertaining to warranty, patent infringement, and limitation of liability.

WM warrants performance of its products to the specifications applicable at the time of sale in accordance with WM’s standard warranty. Testing and other quality control techniques are utilised to the extent WM deems necessary to support this warranty. Specific testing of all parameters of each device is not necessarily performed, except those mandated by government requirements.

In order to minimise risks associated with customer applications, adequate design and operating safeguards must be used by the customer to minimise inherent or procedural hazards. Wolfson products are not authorised for use as critical components in life support devices or systems without the express written approval of an officer of the company. Life support devices or systems are devices or systems that are intended for surgical implant into the body, or support or sustain life, and whose failure to perform when properly used in accordance with instructions for use provided, can be reasonably expected to result in a significant injury to the user. A critical component is any component of a life support device or system whose failure to perform can be reasonably expected to cause the failure of the life support device or system, or to affect its safety or effectiveness.

WM assumes no liability for applications assistance or customer product design. WM does not warrant or represent that any license, either express or implied, is granted under any patent right, copyright, mask work right, or other intellectual property right of WM covering or relating to any combination, machine, or process in which such products or services might be or are used. WM’s publication of information regarding any third party’s products or services does not constitute WM’s approval, license, warranty or endorsement thereof.

Reproduction of information from the WM web site or datasheets is permissible only if reproduction is without alteration and is accompanied by all associated warranties, conditions, limitations and notices. Representation or reproduction of this information with alteration voids all warranties provided for an associated WM product or service, is an unfair and deceptive business practice, and WM is not responsible nor liable for any such use.

Resale of WM’s products or services with statements different from or beyond the parameters stated by WM for that product or service voids all express and any implied warranties for the associated WM product or service, is an unfair and deceptive business practice, and WM is not responsible nor liable for any such use.
