5-V Stereo DAC with 2-V_{RMS} Ground-Centered Output

Features

- Advanced multibit delta–sigma modulator
- 101 dB A-weighted dynamic range
- –86 dB THD+N
- Single-ended ground-centered analog architecture
  - No DC-blocking capacitors required
  - Integrated inverting charge pump
  - Filtered line-level outputs
  - 2 V_{RMS} full-scale output
- Low-latency digital filtering
- Supports sample rates up to 192 kHz
- 24-bit I²S input
- +5-V analog supply with integrated inverting charge pump and regulator for core logic, and +1.8-V to +5-V interface power supplies
- 50-mW power consumption
- 14-pin SOIC, lead-free assembly

Description

The CS4354 is a complete stereo digital-to-analog system including digital interpolation, third-order multi-bit delta–sigma digital-to-analog conversion, digital de-emphasis, analog filtering, and on-chip 2 V_{RMS} line-level driver from a 5 V supply.

The advantages of this architecture include ideal differential linearity, no distortion mechanisms due to resistor matching errors, no linearity drift over time and temperature, high tolerance to clock jitter, and a minimal set of external components.

These features are ideal for cost-sensitive, two-channel audio systems including video game consoles, Blu-Ray Disc® and DVD players, set-top boxes, digital TVs, and DAB/DMB devices.

The CS4354 is available in a 14-pin SOIC package in Commercial (–40°C to +85°C) grade. The CDB4354 Customer Demonstration Board is also available for device evaluation and implementation suggestions. Please see “Ordering Information” on page 23 for complete details.

</tr>
</tbody>
</table>

Notes: 1. Device functional operation is guaranteed within these limits. Functionality is not guaranteed or implied outside of these limits. Operation outside of these limits may adversely affect device reliability.

ABSOLUTE MAXIMUM RATINGS
GND = 0 V; all voltages with respect to ground.

<table>
<thead>
<tr>
<th>Parameters</th>
<th>Symbol</th>
<th>Min</th>
<th>Max</th>
<th>Units</th>
</tr>
</thead>
<tbody>
<tr>
<td>DC power supply</td>

**Notes:**

3. Measured at the output of the external low-pass filter on AOUTx as shown in Figure 5 on page 12.
4. Measured between the AOUTx and GND pins.
5. One LSB of triangular PDF dither is added to data.
6. Does not include attenuation due to \( Z_{\text{OUT}} \). Additional impedance between the AOUTx pin and the load will lower the voltage delivered to the load.
7. \( V_{pp} \) is the controlling specification. \( V_{\text{RMS}} \) specification valid for sine wave signals only.

Note that for sine wave signals: \( V_{\text{RMS}} = \frac{V_{pp}}{2\sqrt{2}} \)
COMBINED DIGITAL AND ON-CHIP ANALOG FILTER CHARACTERISTICS

The filter characteristics have been normalized to the sample rate (Fs) and can be referenced to the desired sample rate by multiplying the given characteristic by Fs. Reference level (0 dB) is set at 997 Hz. *(Note 11)*

</tbody>
</table>

**Notes:**

8. Response is clock-dependent and will scale with Fs.

9. For Single- and Double-Speed Mode, the Measurement Bandwidth is from stopband to 3 Fs. For Quad-Speed Mode, the Measurement Bandwidth is from stopband to 1.34 Fs.

10. De-emphasis is available only in Single-Speed Mode.

11. Amplitude vs. frequency plots of this data are available in “Combined Digital and On-chip Analog Filter Response Plots” on page 20.
12. Not all sample rates are supported for all clock ratios. See Section 4.2 "Sample Rate Range/Operational Mode Detect" on page 13 for supported ratios and frequencies. SSM = Single-Speed Mode, DSM = Double-Speed Mode, QSM = Quad-Speed Mode.

13. SCLK period is defined by the SCLK / LRCK ratio. The SCLK/LRCK ratio may be either 32, 48, or 64. See Table 5 on page 14.

14. \[ t_{sclk} = \frac{t_{sclkw}}{2} + \frac{10^9}{2 \times MCLK} + t_{mclkf} \]

Notes:
15. Power supply current increases with increasing sample rate and increasing MCLK frequency. Typical values are based on Fs = 48 kHz and MCLK = 12.288 MHz. Maximum values are based on highest sample rate and highest MCLK frequency; see “Switching Specifications - Serial Audio Interface” on page 8. Variance between speed modes is small.
16. During normal operation, SDIN = 997 Hz sine wave at 0 dBFS with load resistance R_L = 3 kΩ.
17. Power-down is defined as all clock and data lines held static low. All digital inputs have a weak pull-down (approximately 50 kΩ) which is only present during power on reset. Opposing this pull-down will increase the power-down current.
18. Valid with the recommended capacitor values as shown in the “Typical Connection Diagram” on page 12.

2.1 Digital I/O Pin Characteristics

Input and output levels and associated typical power supply voltage are shown in Table 2. Logic levels should not exceed the corresponding power supply voltage.

Table 2. Digital I/O Pin Characteristics
Figure 5. Typical Connection Diagram
4. APPLICATIONS

4.1 Ground-Centered Line Outputs

An on-chip charge pump creates a negative supply which allows the full-scale output swing to be centered around ground. This eliminates the need for large DC-blocking capacitors which create audible pops at power-on and provides improved low frequency response. See the DAC Analog Characteristics table for the complete specifications of the full-scale output voltage. It should be noted that external output impedance between the AOUTx pin and the load will lower the voltage delivered to the load.

4.2 Sample Rate Range/Operational Mode Detect

The CS4354 operates in one of three operational modes. The device will auto-detect the correct mode when the input sample rate (Fs), defined by the LRCK frequency, falls within one of the ranges illustrated in Table 3. Sample rates outside the specified range for each mode are not supported. In addition to a valid LRCK frequency, a valid serial clock (SCLK) and master clock (MCLK) must also be applied to the device for speed mode auto-detection; see Figure 9.

<table>
<thead>
<tr>
<th>Input Sample Rate (Fs)</th>
<th>Mode</th>
</tr>
</thead>
<tbody>
<tr>
<td>30 kHz - 54 kHz</td>
<td>Single-Speed Mode</td>
</tr>
<tr>
<td>84 kHz - 108 kHz</td>
<td>Double-Speed Mode</td>
</tr>
<tr>
<td>170 kHz - 216 kHz</td>
<td>Quad-Speed Mode</td>
</tr>
</tbody>
</table>

Table 3. CS4354 Operational Mode Auto-Detect

4.3 System Clocking

The device requires external generation of the master (MCLK), left/right (LRCK) and serial (SCLK) clocks. The left/right clock, defined also as the input sample rate (Fs), must be synchronously derived from the MCLK signal according to specified ratios. The specified ratios of MCLK to LRCK, along with several standard audio sample rates and the required MCLK frequency, are illustrated in Table 4 on page 13.

Refer to Section 4.6 for the required SCLK timing associated with the selected Digital Interface Format and to “Switching Specifications - Serial Audio Interface” on page 8 for the maximum allowed clock frequencies.

Table 4. Common MCLK and LRCK Frequencies
4.4 Serial Clock

The serial clock controls the shifting of data into the input data buffers. The CS4354 supports both external and internal serial clock generation modes. Refer to Figure 6 for a diagram of the I²S data format.

In order to support selectable de-emphasis without a dedicated pin, pin 5 (SCLK/DEM) functions both as a serial clock input and a de-emphasis select. In typical applications where de-emphasis is not required, the SCLK/DEM pin is the input for an external serial clock - this is known as the External Serial Clock Mode. To enable de-emphasis selection, the Internal Serial Clock Mode has to be used. Sections 4.4.1 and 4.4.2 describe this feature in detail.

4.4.1 External Serial Clock Mode

The CS4354 will enter the External Serial Clock Mode when 16 low to high transitions are detected on the SCLK/DEM pin during any phase of the LRCK period. When this mode is enabled, the Internal Serial Clock Mode and de-emphasis filter are disabled (see Figure 9 for flow diagram).

In the External Serial Clock Mode, the CS4354 will support up to 24-bit I²S data, with data valid on the rising edge of SCLK.

4.4.2 Internal Serial Clock Mode

The CS4354 will switch to Internal Serial Clock Mode if no low to high transitions are detected on the SCLK/DEM pin for 2 consecutive frames of LRCK (see Figure 9 for flow diagram). In the Internal Serial Clock Mode, the serial clock is internally derived and synchronous with MCLK and LRCK. The SCLK/LRCK frequency ratio is either 32, 48, or 64 depending on the speed mode and MCLK frequency. Operation in this mode is identical to operation with an external serial clock synchronized with LRCK. This mode allows access to the digital de-emphasis function. Refer to Table 5 for details (all frequencies listed as multiples of LRCK frequency).

Table 5. Internal SCLK Frequencies

4.4.2.1 De-Emphasis Control

The device includes on-chip digital de-emphasis. Figure 7 shows the de-emphasis curve for Fs equal to 44.1 kHz. The frequency response of the de-emphasis curve scales with changes in the sample rate, Fs. The de-emphasis error will increase for sample rates other than 44.1 kHz.

When the SCLK/DEM pin is connected to VL (internal SCLK mode), the 44.1 kHz de-emphasis filter is activated. When the SCLK/DEM pin is connected to GND, the de-emphasis filter is disabled. For more information see "Internal Serial Clock Mode" on page 14.

De-emphasis selection is disabled in the external SCLK mode.
4.5 Internal High-Pass Filter

The CS4354 includes an internal digital high-pass filter. This filter prevents a constant digital offset from creating a DC voltage on the analog output pins. The filter’s corner frequency is well below the audio band; see “Combined Digital and On-Chip Analog Filter Characteristics” on page 7 for filter specifications.

4.6 Digital Interface Format

The device accepts audio samples in the industry standard I²S format only.

For an illustration of the required relationship between the LRCK, SCLK and SDIN, see Figure 6 on page 14. SDIN is valid on the rising edge of SCLK. For more information about serial audio formats, refer to Cirrus Logic Application Note AN282: The 2-Channel Serial Audio Interface: A Tutorial, available at http://www.cirrus.com.

4.7 Internal Power-On Reset

The CS4354 features an internal power-on reset (POR) circuit. This circuit monitors the VA supply and automatically asserts or releases an internal reset of the DAC’s digital circuitry when the supply reaches defined thresholds (see “Internal Power-On Reset Threshold Voltages” on page 10). No external clocks are required for the POR circuit to function.
When power is first applied, the POR circuit monitors the VA supply voltage to determine when it reaches a defined threshold, $V_{on1}$. At this time, the POR circuit asserts the internal reset low, resetting all of the digital circuitry. Once the VA supply reaches the secondary threshold, $V_{on2}$, the POR circuit releases the internal reset.

When power is removed and the VA voltage reaches a defined threshold, $V_{off}$, the POR circuit asserts the internal reset low, resetting all of the digital circuitry.

**Note:** For correct operation of the internal POR circuit, the voltage on VL must rise before or simultaneously with VA.

### 4.8 Initialization

When power is first applied, the DAC enters a reset (low power) state at the beginning of the initialization sequence. In this state, the AOUTx pins are weakly pulled to ground and FILT+ is connected to GND.

The device will remain in the reset state until $V_{ON2}$ is reached. Once $V_{ON2}$ is reached, the internal digital circuitry is reset and the DAC enters a power-down state until MCLK is applied.

Once MCLK is valid, the device enters an initialization state in which the charge pump powers up and charges the capacitors for the negative voltage supply.

Once LRCK is valid, the number of MCLK cycles is counted relative to the LRCK period to determine the MCLK/LRCK frequency ratio. Next, the device enters the power-up state in which the interpolation filters and delta-sigma modulators are turned on, the internal voltage reference, FILT+, powers up to normal operation, the analog output pull-down resistors are removed, and power is applied to the output amplifiers.

If a valid SCLK is applied, the device will clock in data according to the applied SCLK. If no SCLK is present, the device will clock in data using the derived internal SCLK (see Figure 3 on page 9) and will apply the de-emphasis filter according to Section 4.4.2.1 on page 14.

After this power-up state sequence is complete, normal operation begins and analog output is generated.

If valid MCLK, LRCK, and SCLK are applied to the DAC before $V_{ON2}$ is reached, the total time from $V_{ON2}$ to the analog audio output from AOUTx is less than 50 ms.

See Figure 9 for a diagram of the device’s states and transition conditions.
Figure 9. Initialization and Power-Down Sequence Diagram
4.9 Recommended Operational Sequences

The following sequences are recommended for minimal pops and clicks when transitioning between different states of operation.

4.9.1 Power-Up

1. Turn on power supplies.
2. Wait for power supply voltages to stabilize.
3. Apply the serial port clocks and data.
   
   Provide the correct MCLK, LRCK, and SCLK (only in External Serial Clock Mode); please refer to Section 4.4 on page 14 for common clock frequencies in the External Serial Clock Mode, and supported modes in the Internal Serial Clock Mode. The sequence will complete and audio will be output from the AOUTx pins within 50 ms after valid clocks are applied.

4.9.2 Power-Down

1. Stop LRCK.
2. Wait 5 ms.
3. Stop MCLK without applying any glitched pulses to the MCLK pin.
   
   A glitched pulse is any pulse that is shorter than the period defined by the minimum/maximum MCLK signal duty cycle specification and the nominal frequency of the input MCLK signal. A transient may occur on the analog outputs if the MCLK signal duty cycle specification is violated when the MCLK signal is removed during normal operation; see “Switching Specifications - Serial Audio Interface” on page 8.
4. Turn off power supplies.

4.9.3 Sample Rate Change

1. Stop LRCK.
2. Wait 5 ms.
3. Stop MCLK without applying any glitched pulses to the MCLK pin.
   
   A glitched pulse is any pulse that is shorter than the period defined by the minimum/maximum MCLK signal duty cycle specification and the nominal frequency of the input MCLK signal. A transient may occur on the analog outputs if the MCLK signal duty cycle specification is violated when the MCLK signal is removed during normal operation; see “Switching Specifications - Serial Audio Interface” on page 8.
4. Wait 2 ms.
   
   This wait time is dictated by the discharge time of the recommended 2.2 µF FILT+ capacitor (see Typical Connection Diagram on page 12). Higher capacitance values will require longer wait times.
5. Apply the serial port clocks and data.
   
   Provide the correct MCLK, LRCK, and SCLK (only in External Serial Clock Mode); please refer to Section 4.4 on page 14 for common clock frequencies in the External Serial Clock Mode, and supported modes in the Internal Serial Clock Mode. The sequence will complete, and audio will be output from the AOUTx pins within 50 ms after valid clocks are applied.

4.10 Grounding and Power Supply Arrangements

As with any high-resolution converter, the CS4354 requires careful attention to power supply and grounding arrangements if its potential performance is to be realized. The “Typical Connection Diagram” on page 12
shows the recommended power arrangements with VA and VL connected to clean supplies. It is strongly recommended that a single ground plane be used with the GND pins connected to the common plane; this is important because both pin 6 and pin 10 provide analog ground reference to the CS4354. Should it be necessary to split the ground planes, the CS4354 should be placed entirely in the analog plane. In this configuration, it is critical that the digital and analog ground planes be tied together with a low-impedance connection, ideally a strip of copper on the printed circuit board, at a single point near the CS4354.

All signals, especially clocks, should be kept away from the FILT+ pin in order to avoid unwanted coupling into the DAC.

4.10.1 Capacitor Placement

Decoupling capacitors should be placed as close to the device as possible, with the low-value ceramic capacitor being the closest. To further minimize impedance, these capacitors should be located on the same PCB layer as the device. See DC Electrical Characteristics for the voltage present across pin pairs. This is useful for choosing appropriate capacitor voltage ratings and orientation if electrolytic capacitors are used.

The CDB4354 evaluation board demonstrates the optimum layout and power supply arrangements.

6. PARAMETER DEFINITIONS

Dynamic Range

The ratio of the full-scale RMS value of the signal to the RMS sum of all other spectral components over the specified bandwidth. Dynamic range is a signal-to-noise measurement over the specified bandwidth made with a -60 dBFS signal. 60 dB is then added to the resulting measurement to refer the measurement to full scale. This technique ensures that the distortion components are below the noise level and do not affect the measurement. This measurement technique has been accepted by the Audio Engineering Society, AES17-1991, and the Electronic Industries Association of Japan, EIAJ CP-307.

Gain Drift

The change in gain value with temperature. Units in ppm/°C.

Interchannel Gain Mismatch

The gain difference between left and right channels. Units in decibels.

Interchannel Isolation

A measure of crosstalk between the left and right channels. Measured for each channel at the converter's output with all zeros to the input under test and a full-scale signal applied to the other channel. Units in decibels.

Total Harmonic Distortion + Noise (THD+N)

The ratio of the RMS value of the signal to the RMS sum of all other spectral components over the specified bandwidth (typically 10 Hz to 20 kHz), including distortion components. Expressed in decibels.
